- 5 Conclusions**

Introduction

Acoustic sensor network

- Consists of sensor nodes connected by wire or wirelessly
- Nodes record (multi-)channel audio signals and process them
- Applications: ad-hoc teleconferencing, monitoring, surveillance

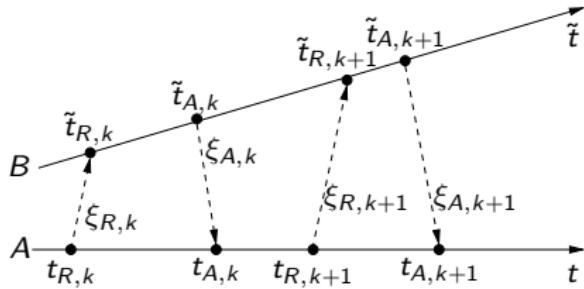

Problem statement

- Sampling clock oscillators at nodes differ typically by ± 50 ppm
 - ⇒ Time base of nodes diverges rapidly
 - ⇒ Precludes application of certain algorithms (e.g. TDOA estimation across sensor nodes)

Our approach

- Estimate clock frequency and phase offset via time stamp exchange protocol
- Improve estimate by Kalman Filter with dedicated error model
- Adjust sampling frequency through direct digital synthesis (DDS) on hardware platform

Clock Frequency Offset Estimation

Time stamp exchange

- Times at nodes A and B

$$\tilde{t}_{R,k} = (t_{R,k} + \xi_{R,k}) \cdot \omega + \varphi$$

$$\tilde{t}_{A,k} = (t_{A,k} - \xi_{A,k}) \cdot \omega + \varphi$$

- ω : clock freq. offset ($\omega = 1$: perfect sync.)

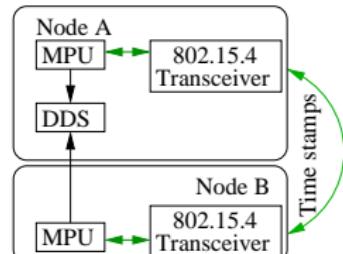

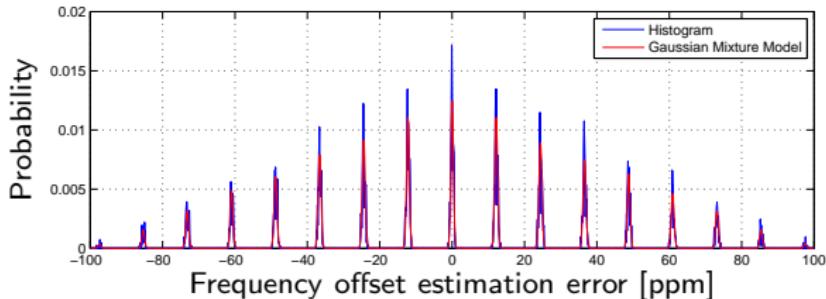

Clock Frequency Offset Estimation [Chaudhari 2012]

$$\frac{\Delta \tilde{t}^+}{\Delta t^+} = \frac{\tilde{t}_{R,k+1} - \tilde{t}_{A,k}}{t_{R,k+1} - t_{A,k}} = \left(1 + \frac{\xi_{R,k+1} + \xi_{A,k}}{t_{R,k+1} - t_{A,k}} \right) \omega \quad \text{and} \quad \frac{\Delta \tilde{t}^-}{\Delta t^-} = \left(1 - \frac{\xi_{R,k} + \xi_{A,k+1}}{|t_{R,k} - t_{A,k+1}|} \right) \omega$$

$$\hat{\omega} = \frac{\Delta \tilde{t}^+ - \Delta \tilde{t}^-}{\Delta t^+ - \Delta t^-} = \left(1 + \frac{(\xi_{R,k+1} - \xi_{R,k}) + (\xi_{A,k} - \xi_{A,k+1})}{(t_{R,k+1} - t_{R,k}) + (t_{A,k+1} - t_{A,k})} \right) \omega$$

- Influence of transmission times vanishes with increasing temporal distance between k -th and $(k + 1)$ -st time stamp exchange

Transmission Error Model

Experiment: Two nodes connected to a single crystal oscillator

- Measured observation error distribution $p(\hat{\omega}|\omega = 0)$ (6 hours of data)
- Two types of errors
 - Large-scale: Packet losses, protocol dependent wait states, medium access control (caused by network)
 - Small-scale: Estimation error of time stamp exchange protocol, MPU hardware interrupts, I/O latencies
- Gaussian mixture model (GMM) to approximate measured histogram

$$p(v_o) = \sum_{k=1}^K p(k)p(v_o|k) = \sum_{k=1}^K \gamma_k \mathcal{N}(v_o; \mu_{k,o}, \sigma_{k,o}^2)$$
- GMM trained offline

Kalman Filter (1/2)

Kalman filter

- Simple kinematic model to model oscillator frequency drifts ($\mathbf{x} = [\omega, \Delta\omega]^T$)

$$\mathbf{x}(n+1) = \underbrace{\begin{bmatrix} 1 & T \\ 0 & 1 \end{bmatrix}}_{\mathbf{F}} \mathbf{x}(n) + \underbrace{\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}}_{\mathbf{G}} \cdot \underbrace{\begin{bmatrix} 0 \\ v_s(n) \end{bmatrix}}_{\mathbf{v}_s}$$

- Measurement equation: $z(n) := \hat{\omega}(n) = \underbrace{\begin{bmatrix} 1 & 0 \end{bmatrix}}_{\mathbf{H}^T} \mathbf{x}(n) + v_o(n)$
- Minimum mean square error (MMSE) estimate of the system state

$$\hat{\mathbf{x}}(n|n) = \hat{\mathbf{x}}(n|n-1) + \mathbf{K}(n) \cdot \left(z(n) - \mathbf{H}^T \hat{\mathbf{x}}(n|n-1) - E[v_o(n)] \right)$$

- Predicted MMSE estimate of frequency offset

$$\hat{\omega}^{(KF)}(n) = \mathbf{H}^T \hat{\mathbf{x}}(n|n-1)$$

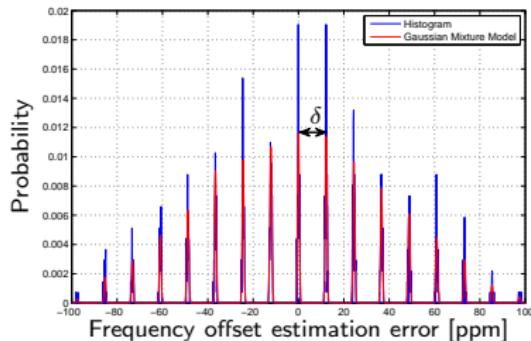

Kalman filter (2/2)

Assumption

- Kalman filter prediction $\hat{\omega}^{(KF)}(n)$ is close to true value ω

$$|\hat{\omega}^{(KF)}(n) - \omega| \ll \delta,$$

- $\delta = \min_{k,I} |\mu_{k,o} - \mu_{I,o}|$

Removal of large-scale observation errors

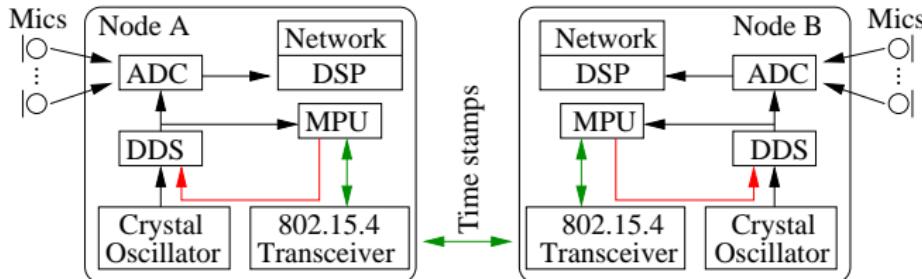

- Contributions of large scale effects to the observation error can be identified

$$\hat{k} = \operatorname{argmin}_k \left| \hat{\omega}^{(KF)}(n) - \mu_{k,o} \right| = \operatorname{argmax}_k p(v_o|k)$$

- Large-scale observation error can be removed:

$$\hat{x}(n|n) = \hat{x}(n|n-1) + \mathbf{K}(n) \left((z(n) - \mu_{\hat{k},o}) - \mathbf{H}^T \hat{x}(n|n-1) \right)$$

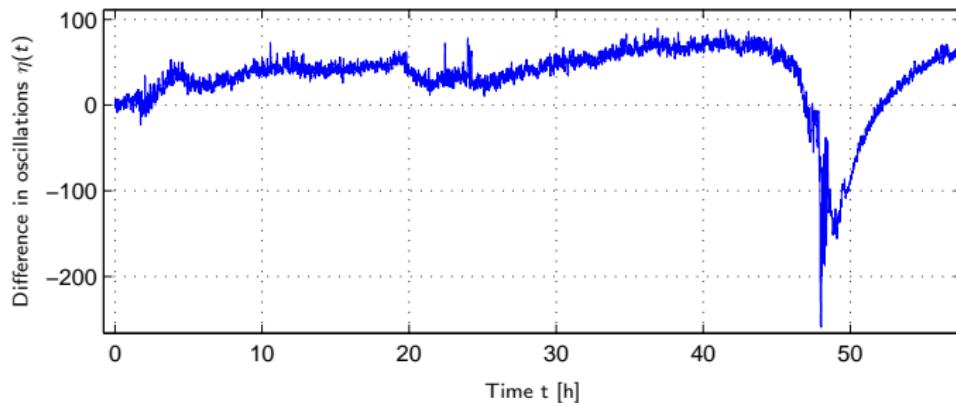

Hardware platform

Hardware platform

- Network-connected multi-channel acoustic sensor nodes (own development)
- ADC with an oversampling factor of 512 to generate a 16 kHz sampling rate
- Direct Digital Synthesis (DDS): Generates arbitrary frequencies with sub-hertz resolution: $0.0279 \text{ Hz} \hat{=} 0.00341 \text{ ppm} @ 16 \text{ kHz}$
- Time stamps: MPU counts oscillations
- Time stamp exchange via wireless link (IEEE 802.15.4 MAC & physical layer)
- Stacked on top: BeagleBoard XM (DSP & Ethernet connection)

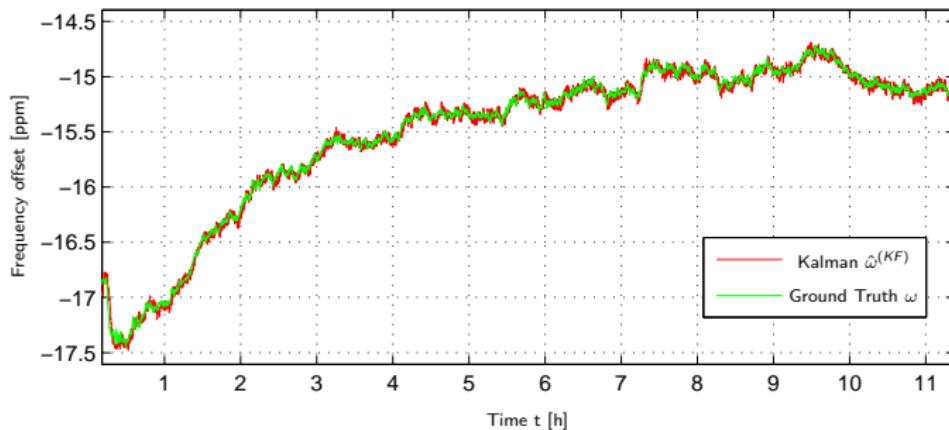

Experiment on Wired Connection

Setup: Wired connection, DDS of slave node adjusted

- USART connection between two sensor nodes for time stamp exchange
 - ▶ Absence of large-scale errors: GMM turns into single Gaussian distribution
- Difference in oscillations:
$$\eta(t) = \int_0^t (f_M(\tau) - f_S^{(A)}(\tau)) d\tau$$
 - ▶ $f_M(t)$: Frequency of master node
 - ▶ $f_S^{(A)}(t)$: Adjusted frequency of slave node
- Maximum difference was kept below 250 oscillations
 - ⇒ Maximum sampling error below a half sample (oversampling factor of 512!)

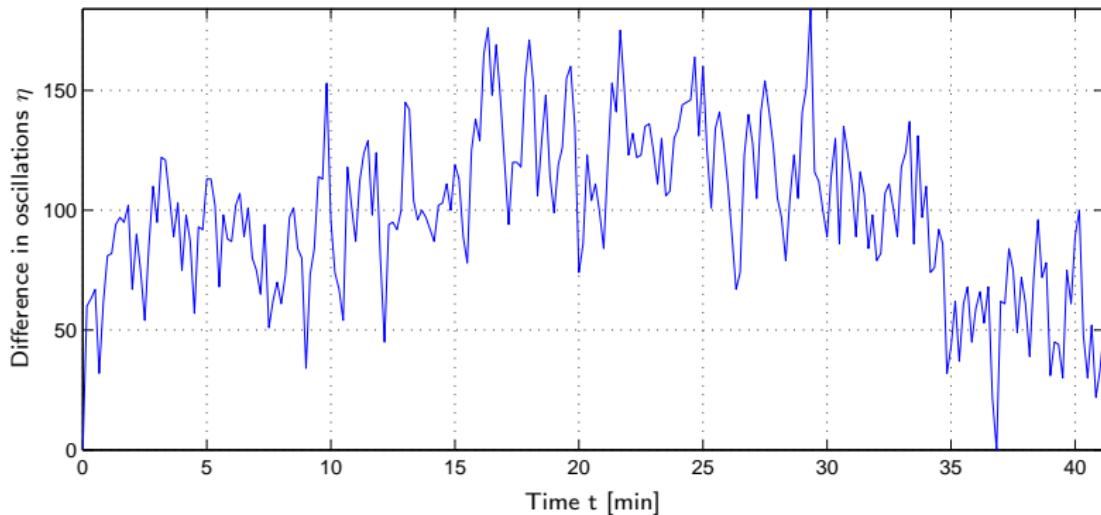

Experiment (1/2) on Wireless Connection

Setup: wireless connection, DDS not adjusted

- Wireless 802.15.4 connection (ZigBee)
- Comparison between
 - ▶ Ground truth $\omega(n)$ (measured by extra hardware device)
 - ▶ Kalman filter estimate $\hat{\omega}^{(KF)}(n)$
- Mean square error was measured to be 0.0019 ppm

Experiment (2/2) on Wireless Connection

Setup: wireless connection, DDS adjusted

- Wireless 802.15.4 connection (ZigBee)
- Difference between data streams remains below $180/512 = 0.35$ samples
- Network load caused by exchange of 64-Bit time stamps each 10 s:
 $4 \cdot 64 \text{ Bit}/10 \text{ s} = 25.6 \text{ Bit/s}$

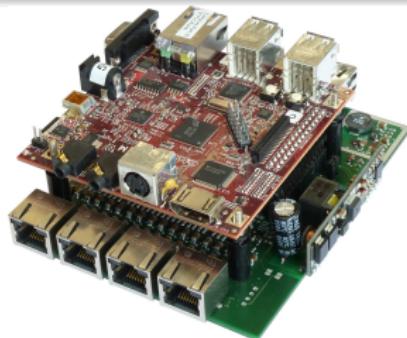

Conclusions and Outlook

Conclusions

- Clock frequency synchronisation of distributed sensor nodes by time stamp exchange protocol
- Improved clock frequency offset estimates by post filter
 - ▶ Kalman filter which exploits the characteristics of the estimation error
- Implementation on microprocessor units
- Communication via an IEEE 802.15.4 wireless network
- Low network load by time stamp exchange
- Long term experiments: Difference between two data streams is kept below a maximum of half a sample

Outlook

- Improved feedback control
- Online error model estimation
